From: Bettina Pedemonte and Elisabetta Robotti, Aspetti linguistici della dimostrazione (Linguistic Aspects of Proof), *Notiziario Unione Matematica Italiana*, **XXXI**, No. 10, October, 2004, pp. 12–30.

2. ABC is an arbitrary triangle. On the exterior of each side of the triangle, a square is constructed. Joining the free corners of each square, three new triangles are created.

Compare the area of each of the three new triangles with the area of the triangle ABC .

Discussion: Put some additional labels on the figure.

Compare the areas of $\triangle ABC$ and $\triangle GCI$.

$$\begin{aligned}\text{Area}(\triangle ABC) &= \frac{1}{2}bh \\ &= \frac{1}{2}CB \cdot AP, \\ \text{Area}(\triangle GCI) &= \frac{1}{2}IC \cdot GQ.\end{aligned}$$

Note that $CB = IC$, and $\triangle GQC \cong \triangle APC$ so that $AP = GQ$. Hence

$$\text{Area}(\triangle ABC) = \text{Area}(\triangle GCI).$$

More...

One might ask if the argument works if $\angle ACB$ is obtuse (here $\approx 117^\circ$).

Yes!
